## Homework 2

AI 539 - Machine Learning for Non-AI Majors Instructor: Alireza Aghasi Due date: See Canvas

April 19, 2024

Please revise the homework guidelines reviewed in the first lecture. Specifically note that:

- Start working on the homework early
- Late homework is not accepted and will receive zero credit.
- Each student must write up and turn in their own solutions
- (IMPORTANT) If you solve a question together with another colleague, each need to write up your own solution and need to list the name of people who you discussed the problem with on the first page of the material turned in
- The homework should be manageable given the material lectured in the class. The long questions are to help clarifying the problem.

**Q1.** (a) We take n independent samples  $x_1, x_2, \ldots, x_n$  from the distribution:

$$f(x) = \frac{2x}{\lambda^2} \exp\left(-\left(\frac{x}{\lambda}\right)^2\right).$$

The goal is estimating the unknown parameter  $\lambda$ .

- (a) Derive the maximum likelihood estimates of  $\lambda$  in terms of the samples  $x_1, x_2, \ldots, x_n$ . Notice that  $\lambda \neq 0$ , and you would need this assumption to estimate  $\lambda$  without too much work.
  - (b) Suppose that n=3, and  $x_1=1.35, x_2=2.76, x_3=3.12$ . Evaluate your ML estimate  $\hat{\lambda}$ .
  - **Q2.** We take n independent samples  $x_1, x_2, \ldots, x_n$  from the distribution

$$f(x) = \frac{\exp\left(-\frac{x-\alpha}{\beta}\right)}{\beta\left(1 + \exp\left(-\frac{x-\alpha}{\beta}\right)\right)^2}.$$

The goal is estimating the parameters  $\alpha$  and  $\beta$  based on the observed samples  $x_1, x_2, \ldots, x_n$ . We would not be able to find closed-form expressions for the ML estimates of  $\alpha$  and  $\beta$ , and need to consider a numerical minimization technique. Let's go through this task step by step.

(a) Formulate the likelihood function

$$f(x_1,\ldots,x_n|\alpha,\beta)=\ldots$$

(b) Formulate the negative log-likelihood function

$$L(\alpha, \beta) = -\log (f(x_1, \dots, x_n | \alpha, \beta)).$$

To estimate the ML estimates  $\hat{\alpha}$  and  $\hat{\beta}$  we can minimize the negative log likelihood function  $L(\lambda, \alpha)$ . For this purpose we decide to use a gradient descent scheme. Derive the expression for the gradient components below:

$$\frac{\partial L}{\partial \alpha} = \dots, \qquad \frac{\partial L}{\partial \beta} = \dots$$
 (1)

(c) Suppose that n=5, and  $x_1=0.30753, x_2=0.56678, x_3=-0.25177, x_4=0.37243, x_5=0.26375$ . Use the Matlab or Python 3D surface tools to plot  $L(\alpha, \beta)$  as a function of  $\alpha$  and  $\beta$ , in the following region:

$$0.2 \le \alpha \le 0.4$$
,  $0.1 \le \beta \le 0.2$ .

- (d) Again, suppose that n=5, and  $x_1=0.30753, x_2=0.56678, x_3=-0.25177, x_4=0.37243, x_5=0.26375$ . Pick a programming language of your choice and write up a gradient descent (GD) scheme using the gradient components you derived in (1). For your scheme set the gradient learning rate to  $\eta=0.001$ , and use the initial values  $\alpha_0=2$  and  $\beta_0=2$ . Run the GD scheme for 1000 iterates, and report the final estimates of  $\alpha$  and  $\beta$ . Also provide a plot showing the iterative values of  $\alpha$  for the iterates from 1 to 1000. Provide a similar plot showing the iterative values of  $\beta$  for the iterates from 1 to 1000. Also attach your code.
- (e) Use an exact same setup as part (d), but this time in your gradient descent scheme use a momentum term of  $\gamma = 0.9$ . Report the final estimates of  $\alpha$  and  $\beta$ . Also provide a plot showing the iterative values of  $\alpha$  for the iterates from 1 to 1000. Provide a similar plot showing the iterative values of  $\beta$  for the iterates from 1 to 1000. Comparing these plots with those in part (d), which scheme seems to have converged faster? Attach your code.
